Composition of tension (Seruuma Manuscript 2026)

Seruuma's law of Tension.

Tension exists in two components; A linear and circular components, orthogonal to each other, and related in magnitude and direction. Changing the direction of linear tension at a point, automatically changes the direction of the corresponding circular tension.

At every instance of time, linear tension at a point, corresponds with a recurrence of linear and circular components in succession (each leading to the other,) along the plane perpendicular to the initial linear tension, and spreading in attenuation away from the point.

Instances of tension.

All known fields, like magnetic fields, electric fields, mechanical fields and gravitational fields, are actually tension fields.

A tension field describes the characteristics and specifics of a path of influence along which a specific entity of existence like charge, or matter, experiences tension.

A specific form of tension influences a specific entity of existence. For example, magnetic and electric tensions influence charge. While mechanic and gravitation tensions influence matter.

In waves, ripples are the direct consequence of tension recurrence.

In electricity, potential difference across a wire is linear tension, while the circular electric field around the wire is the circular component of the electric tension.

In mechanics, objects in orbit experience gravitation tension with a linear component along the orbit radius and its corresponding circular component.

Spinning of objects in orbit is the result of a circular component of orbit tension.
